(54) Title: METHOD OF CUTTING A SHEET AND REDUCING THE REMNANT MATERIAL

(57) Abstract: The invention relates to a method of cutting a sheet-like piece into one or several smaller pieces by using camera means and a controllable cutting apparatus, the directions and values of the coordinate systems of which are calibrated to correspond to each other. In the method following measures are taken: the piece to be cut is placed on a cutting surface located within the recording area of the camera means, the piece is photographed by the camera means and on the basis thereof the outlines of the piece are determined and the information on the outlines of the piece is input into the positioning system, where the cutting paths are established and input into the control system of the cutting device, which determines necessary parameters for the cutting and on the basis of these, controls the cutting of the piece into parts according to given instructions.

METHOD OF CUTTING A SHEET AND REDUCING THE REMNANT MATERIAL

The invention relates to a method of cutting a sheet-like piece by utilizing
5 camera means and a controllable cutting apparatus in accordance with the
preamble of claim 1.

A lot of so-called remnant sheet is produced by the shipbuilding work, when
larger sheet objects are manufactured by thermal cutting. On the other hand
10 a ship comprises a great number of small standard components, the annual
need of which is several thousands of pieces, and the aim is to use remnant
sheet as a material for these components, where possible. While manufac-
turing standard components, the machine operator has to use excessively
much time for utilizing the remnant pieces. Today, the utilization of remnant
15 sheet is not cost-effective from the technical and economical point of view
and the problem when using remnant material has been the difficulty in posi-
tioning standard components on a remnant sheet having an irregular shape,
and thus the scrub percentage has been fairly high. Conventionally, the utili-
zation of remnant material has stayed on a level, where the machine operator
20 measures by hand a rectangular area on the remnant sheets, inputs the data
into the machine control and starts positioning components on the defined
area. Being a task of the machine operator the positioning is in its present
form far too time-consuming, and the outcome is not economical in terms of
working hours and consumption of material. In practice, the machine opera-
25 tor has to make also a physical effort when taking the cutting machine to the
starting point of the cutting program.

An aim of the present invention is to overcome the disadvantages related to
prior art and provide a novel solution, where said disadvantages can be elimi-
30 nated as efficiently as possible.

The aim of the invention can be achieved as is described in claim 1 and in the other claims.

According to the invention following measures are taken: the piece to be cut
5 is placed on a cutting surface located within the recording area of camera means, the piece is photographed by the camera means and on the basis thereof the outlines of the piece are determined and the information on the outlines of the piece is input into the positioning system, where the cutting paths are established and input into the control system of the cutting machine, which determines necessary parameters for the cutting and on the basis of these, controls the cutting of the piece into parts according to given instructions. Thus, the invention enables the use of machine vision for defining the sheet blank so as to provide and implement a cutting program. Preferably, also automation may be applied to the positioning of the pieces to be cut on the remnant sheet. Thus the invention enables an economical utilization of remnant sheet material in the positioning the pieces to be cut, and minimises manual work and the scrub percentage of the remnant sheet material. Here, the outlines of the piece also refer to the shape of such parts of the pieces, e.g. openings, which remain inside the piece. Also, the invention
15 is preferably applicable to the utilization of remnant sheet objects, which are irregular in shape, in a most optimal way.
20

Once the outlines and dimensions of the piece have been determined, positioning data is created by selecting at least one type of a small part and adding a desired number of said at least one type of small parts to the outline image inside the outlines. For the positioning a suitable program may be used for instance by selecting a certain type of a small part from the macro-library, whereby the program fills the sheet-like piece with said parts. The positioning may also be based on selecting several different kinds of small parts. Alternatively, also the operator himself may draw by the program a desired kind of a small part and place a certain number of these on the sheet-like piece.
25
30

In the automatic positioning on a remnant sheet the cutting paths, starting points and volumes as well as the use of material are optimised. Also the starting point of the cutting and the cutting path may be determined either by the operator or automatically. After the determination, the positioning data is
5 input into the control system of the cutting apparatus, whereby the operation of the cutting machine changes from an incremental, i.e. from a sheet blank specific, coordinate system proportioned to the zero point over to an absolute coordinate system, i.e. to a coordinate system covering the whole work station. A numerically controlled flame cutting machine, a manipulator or a robot
10 is preferably used as a cutting apparatus.

As ancillary equipment while photographing the object, a light source to be reflected, most preferably a laser bar, may be used to facilitate the detectability and/or to provide additional information. In the method according to the
15 invention the working area is illuminated for photographing to such an extent that the illumination conditions are as constant as possible so as to make the outlines and position of the piece visible with sufficient accuracy. The illumination and the bars or matrices to be reflected facilitating the detectability are complementary to each other. The photographing according to the
20 method may be performed by one or several cameras, preferably CCD-cameras, which may be located in the cutting apparatus, in a separate portal moving on the same guide rails as the cutting apparatus or in external structures, e.g. at the ceiling of the working area, or by means of a separate guide rail in outside structures.

25 The pieces to be cut compose parts of a metal structure, which most preferably may be intended for a watercraft, ship or another marine equipment, but the invention may as well be applied to other kinds of objects, where sheet metal pieces are utilized.

30 In the following the invention is described by way of example with reference to the attached drawings, in which

Figure 1 shows a functional diagram for utilizing remnant material in the manufacture of sheet objects; and

5 Figure 2 shows a positioning layout.

In a machining arrangement 1 according to Fig. 1, i.e. in this case thermal cutting, an image of the cutting area 3 of a cutting apparatus is provided by camera means 2 to be attached to a cutting machine, to a separate guide rail
10 or to structures surrounding the machine. The shape and dimensions of the outlines of a sheet blank 4 comprising a remnant sheet and located within the cutting area 3 are determined by means of the image provided by the camera. The sheet blank 4 is placed on a cutting surface 5, which may comprise for instance a floor or a machining table. The determination of the di-
15 mensions may be performed by software according to software algorithms or manually by the operator by pointing at the display. As ancillary equipment for the determination an illumination and a light source to be reflected, preferably a helium-neon laser bar, may be used for facilitating the detectability. The result of the determination is data, i.e. so-called image data 6, including
20 the dimensions of the outlines of the sheet blank 4 and its location in the working area 3, which data is transferred over to a positioning system 7, where a desired number of certain type of small parts is placed on the area. For instance a certain type of a small part may be selected from the macro-library and the positioning program may be arranged so as to fill the sheet
25 blank with said parts. Alternatively, also the operator himself may draw by the program a small part having a desired shape and place a certain number of these parts on the sheet blank, and if desired, a certain number of some other kinds of small parts, if there is still open space on the sheet blank. The positioning data is then input into the control system of the cutting apparatus, which actuates a cutting program 8.
30

The positioning system 7 may be located either on a separate computer 7 or in conjunction with a machine control 9. Information on a sheet blank 4 having any kind of a shape is received easily and fast with the assistance of the system and it is possible to optimise the use of the blank and minimize the scrub percentage by means of computer-based automatic positioning. In addition to the dimensions of the sheet blank 4, the machine vision system is capable of indicating also the position of a reference angle or starting angle in the working area 3 of the cutting apparatus (not shown in detail), whereby a separate relocation of the cutting apparatus, which used to be carried out manually, is unnecessary, and the cutting 10 of the sheet blank 4 may be started. Thus both time and material can be saved by the invention, meanwhile the operation efficiency improves and the costs decrease.

The cutting may be performed by methods known per se, e.g. by gas cutting or plasma cutting. One advantageous method is numerically controlled thermal cutting, where the parameters for cutting, e.g. the cutting speed, the size of the cutting grooves etc., may be determined by numerical control. The cutting apparatus may run itself to the starting point and start the cutting.

Fig. 2 shows an example of a positioning and cutting layout, which may be realized by inputting the layout into a numerically controlled cutting machine. Here, a number of sheet-like small parts 4a, which are all alike, are placed on a sheet blank 4. Some of these could, of course, be replaced by other kinds of parts. The cutting directions are indicated by arrows.

It is evident for a person skilled in the art that the invention is not limited to the above-described application, but various modifications of the invention are conceivable in the scope of the inventive conception defined by the appended claims.

CLAIMS

1. A method of cutting a sheet-like piece into one or several smaller pieces by using camera means and a controllable cutting apparatus, the directions
5 and values of the coordinate systems of which are calibrated to correspond to each other, **characterised** in that following measures are taken:
- the piece to be cut is placed on a cutting surface located within the recording area of the camera means,
 - the piece is photographed by the camera means and on the basis thereof
10 the outlines of the piece are determined,
 - the information on the outlines of the piece is input into the positioning system, where the cutting paths are established and input into the control system of the cutting machine, which determines necessary parameters for the cutting and on the basis of these, controls the cutting of the piece
15 into parts according to given instructions.
2. A method according to claim 1, **characterised** in that once the outlines and dimensions have been determined, positioning data is created by selecting at least one type of a small part and adding a desired number of said at least
20 one type of small parts into the outline image inside the outlines.
3. A method according to claim 2, **characterised** in that also the starting point of the cutting and the cutting path are determined automatically or by operator-aided means, and the positioning data is input into the control system of the cutting apparatus.
25
4. A method according to claim 2 or 3, **characterised** in that in the automatic positioning on the sheet the cutting paths, starting points and volumes as well as the use of material are optimised.
30
5. A method according to any one of the preceding claims, **characterised** in that the operation of the cutting apparatus changes from an incremental, i.e.

a sheet blank specific, coordinate system proportioned to the zero point over to an absolute coordinate system, i.e. to a coordinate system covering the whole work station.

- 5 6. A method according to any one of the preceding claims, **characterised** in that a numerically controlled thermal cutting machine, a manipulator or a robot is used as a cutting apparatus.
7. A method according to any one of the preceding claims, **characterised** in
10 that as ancillary equipment while photographing the object, a light source to be reflected, most preferably a laser bar, may be used to facilitate the detectability and/or to provide additional information.
8. A method according to any one of the preceding claims, **characterised** in
15 that the pieces to be cut compose parts of a metal structure, for instance a watercraft, ship or another marine equipment, a bridge, paper machine, building, vehicle such as a train, lorry, mining vehicle or a tank or a platform structure.
